Our boilers are built with heavy We specialize in the cooling units that power The cooling unit is the set of metal coils that are The three most common If the unit has leaked for anThis would indicate a leakSince this leak is outside the box you wouldI see these boiler leaks more frequentlyThe labor to There are no special tools required, Most people with average mechanical ability I also have a list of

installation. NOTE THAT ALL DOMETIC OEM PARTS ARE LIMITED SUPPLY SINGLE DOOR NOTES
1 Cooling unit for RM2190 RM2150 with freezer. The freezer does a good job of freezing ice and keeping it frozen but the refrigerator is not much below ambient. Gas or electric does not seem to make any difference. The chimney is good and hot to the touch. Any thoughts on why one part would work OK and one would not Even a slight decrease in flame size can have a detrimental affect on cooling performance. It covers the items Brett mentioned and has contact information. I did not find any reference to the sensor, but know there is one in the repair list of parts. Ive been tied up with family matters but will start doing the tests prescribed by Brett and in the manual when I finally arrive home and have some time.

As of this moment the refrigerator seems to be cooling properly and the temp in the refrigerator compartment this morning was 34, which is where it has been until this recent glitch. We have been in very hot weather the last month and have felt the refrigerator has not been cooling the way it should. Unfortunately I have not been able to find any performance specs as to what temps should be and at what ambient temps. The specs on the dometic website do not provide that or I was looking in the wrong spot. Can anyone provide that. My model is a NDR 1292 Mine is a RM3862 in a 2000 Dutch Star. Mine first acted up about 3 weeks ago with the onset of hot weather. Temps above 100F. I put a fan on the outside vent as recommended by a local repair guy. Within 24 hours the temp was down from 63F to about 34F. Worked good for about two weeks. Last week temps went up again both outside the MH and inside the refrigerator. Local guy said to turn off for 24 hours to allow all the chemicals to reform. No luck after that. Freezers freezes good but no cooling in refrig area. He says they arent worth the money. So now I am looking at replacing with a home type refrigerator. If you can try removing the vent cover up on the roof and check for obstructions, Since you did have a fan blowing try putting it back and check to see if you have air flow out the vent. Experienced the same problems. After replacing the control circuit board it is operating like new. Go figure. The Dometic Corporation Industrial Parkway Elkhart, IN No Gas Operation Automatic Reigniter. Operation and Diagnosis Dometic Manual Refrigerators Glossary of Terms Service Bulletins Page D41 D42 D43 D44 D61 D81 D91 D3 THE ABSORPTION SYSTEM 3 The sealed combustion unit contains a mixture of ammonia, water and a rust inhibiting agent. After this solution is introduced into the coils, this unit is pressurized with hydrogen gas.

When this system is in operation, the ammonia vaporizes in the hydrogen atmosphere and absorbs heat from inside the refrigerator. GAS TEMPERATURE EXCHANGER ABSORBER LIQ EVAPORATOR VESSEL BOILER. D62 LP gas, 120 volts AC and 12 volts DC heating elements are the most commonly used heat sources for recreational vehicle applications. These are precise heat, specified ventilation and proper leveling. THREE REQUIREMENTS FOR PROPER OPERATION 1. Level 2. Air Flow Ventilation 3. Heat D64. When proper heat is supplied to the boiler, ammonia vapor is produced and rises in the siphon pump, carrying with it a weak liquid ammonia solution. As seen from this drawing, the siphon pump, or pump tube, is an internal arrangement within the boiler section. The boiler section utilizes the ammoniawater liquid solution in the absorber and as it is heated, turns the solution into a strong ammonia vapor, which is needed to operate the system. This strong ammonia vapor rises from the pump tube to the condenser coil. Any deviation from the listed amount of heat to the absorption system will alter the ammonia to water ratio, which, in turn, will decrease the cooling unit s overall efficiency. The weak ammonia solution which remains behind is diverted to the top of the absorber coils to perform a function that we will discuss in further detail later in the program. As a liquid, it then flows to the low temperature evaporator, or freezer compartment, where it comes into contact with a hydrogen atmosphere. When this occurs, the ammonia begins to evaporate which draws heat from inside the freezer section, to the rear of the cooling unit. COLD NTEROR 12 This heat is then dissipated out through the upper vent, which allows the refrigerators interior temperature to properly maintain food storage requirements. Not all of the liquid ammonia evaporates in the freezer. What is left continues to evaporate as it flows to the high temperature

evaporator, or food storage compartment.

D65 As the ammonia vapor comes in close contact to the liquid ammonia solution in the absorber vessel, the ammonia is absorbed into the liquid solution, allowing the hydrogen vapor to rise up through the absorber coils. After this absorption process, the vapor consists of mostly hydrogen with some traces of ammonia. L14 To remove the remaining amounts of ammonia vapor still present in the hydrogen, a continuous flow of weak ammonia solution is fed, by gravity, to the top of the absorber coil from the boiler. As this weak ammonia solution flows downward through the absorber, it absorbs the ammonia vapor from the mixture, allowing the hydrogen vapor to rise through the absorber coil and return to the evaporator. With the hydrogen returned to the evaporator and the ammonia remixed into solution in the absorber vessel, the cooling process can continue. A15 Now that we have a basic understanding of proper cooling unit flow and operation, let's take a step-by-step look at the three requirements for proper cooling unit operation. Please note it is essential that these three requirements be diagnosed before attempting to diagnose the cooling unit. A problem with leveling, heat input or ventilation may lead you to think that the cooling unit is faulty, when actually it is not. This causes an increased expense to you, the customer, and valuable shop time is wasted because of incorrect diagnosis. By following and checking the three unit requirements, costly diagnostic errors can be eliminated. **THREE REQUIREMENTS FOR PROPER OPERATION** 1. Level 2. Air Flow Ventilation 3. Heat D66 Without proper leveling, refrigerant within the cooling coils will collect and stagnate at certain areas. When this happens the cooling process will stop. **THREE REQUIREMENTS FOR PROPER OPERATION** 1. Level 17 On the older style cooling units equipped with square boiler box covers, this condition can cause permanent cooling unit failure.

As we can see from this drawing, square boiler box cooling units utilize an exposed siphon pump tube which will become excessively superheated in an out-of-level condition. This can allow the rust-inhibiting agent to chemically break down and permanently block or restrict the normal refrigerant flow through the pump. Shaking, tipping or so-called burping the refrigerator will not loosen or dislodge the blockage. The only recommended service procedure is to replace the cooling unit. To prevent this occurrence, proper leveling is of utmost importance when the RV is parked for any length of time. **REFRIGERATOR S TO BE LEVEL** 18 To level these units, the spirit or bubble level should be placed in the approximate front and center of the floor of the freezer compartment. **REMEMBER** Failure to properly level a square boiler box can result in a lack of cooling or permanent damage to the cooling unit. When the vehicle is moving, leveling is not critical as the rolling and pitching movement of the RV will keep the solution in motion, preventing the solution from accumulating in the piping. As we can see from this drawing, the siphon pump tube is enclosed in the design and is surrounded by a weak ammonia solution, which will protect the pump tube from abnormally overheating. This type of unit; however, does not eliminate the need for proper leveling. The unit still requires gravitational flow to provide the proper cooling process, and if leveling is outside the necessary limits, cooling will dramatically slow down or stop completely. The cooling coils are not normally damaged in this fashion and once proper leveling is maintained, the cooling process will resume. \ **PUMP** 20 Spirit or bubble levels are no longer being supplied with the new style refrigerators as the RV or vehicle only needs to be leveled so it is comfortable to live in, with no noticeable sloping of the floor or walls.

For diagnosis, the new style cooling units that incorporate the protection boiler system, can be differentiated from the older style coils by the shape and design of the outer boiler box cover on the rear of the cooling unit. These units will incorporate a circular metal cover. We will discuss diagnosis and troubleshooting of these units in more detail later in the program. **THREE REQUIREMENTS FOR PROPER OPERATION** 1. Level 2. Air Flow Ventilation 23 In a good installation there should be as little open space as possible surrounding the sides and top of the refrigerator to achieve proper air flow. All potential dead air pockets should be blocked or baffled to insure that

heat from the cooling unit won't be trapped in these spaces and reduce efficiency. Please follow the installation manual for proper dimensions and clearances. RVA requires that the refrigerator be installed in such a manner as to provide complete separation of the combustion system and the interior atmosphere of the recreational vehicle. This regulation requires all seams and joints in the enclosure be sealed. The undercounter installation is different. The addition of a metal chute the width of the enclosure, that extends from the upper side vent, will help eliminate the possibility of dead air pockets. The best method for venting the absorption refrigerator is with a lower side vent and a roof vent. Always use the proper size orifice for gas modes. As explained earlier, any deviation will cause a potential cooling unit failure.

THREE REQUIREMENTS FOR PROPER OPERATION

1. Level
2. Air Flow Ventilation
3. Heat

D69 This means proper leveling is important. Second, heat created to boil the ammonia now has to be dissipated into the surrounding air. Heat from the absorber and condenser must also be dissipated so as to cool the ammonia sufficiently. Third, proper heat application at the boiler section.

TEMPERATURE EXCHANGER THE ABSORPTION SYSTEM CONDENSER EVAPORATOR OF BOILER

26 When diagnosing a cooling unit, remember this is the only part we cannot field check with test equipment, yet it is the simplest and quickest part to diagnose.

DAGNOSING THE COOLING UNIT

27 After the unit has been operating for approximately one hour, carefully touch the unit at the boiler box and the absorber area. These areas should be approximately the same temperature, regardless of the ambient temperature. Equal heat between the boiler and the absorber indicates the fluid circulation within the unit is good.

TEMPERATURE b GOOD CIRCULATION

D610 This can happen when the unit is operated off-level, or if too much heat has been applied to the boiler area. To the touch, this unit will be extremely hot at the boiler with little warmth at the absorber. To the touch, this unit will be warm at the boiler and extremely hot at the absorber. Both systems will be covered in this presentation.

D61 1 UNDERSTANDING THE GAS SYSTEM

32 Gas flows from the gas line to the shutoff valve and to the connection piece. Remember that except for the connection piece, all fittings are O-ring sealed. Whenever the system is separated the O-rings must be replaced. With the thermostat on maximum you must have 11 inches water column pressure at this point. When the thermostat is working properly, the manometer will read line pressure when set at maximum and the refrigerator is trying to cool. From this drawing you can see the gas flow when the refrigerator is trying to cool. The gas flows through the thermostat at line pressure without restriction. The valve is open at this time. This condition can only exist when the refrigerator is cold or the thermostat is set to minimum or off. With the thermostat set at maximum you must have 11 to 12 inches water column pressure for the refrigerator to operate properly. Make sure the gas system has at least 50% of the coach's LP appliances on at the time the system is being adjusted.
