Sensor can be used to trigger scenes and everywhere there is a need for information about opening or closing of doors, windows, garage doors, etc. Opening is detected by separating the sensor's body and the magnet. Correct relation of the Sensor and the magnet is marked on the casing. If adequately protected, the DS18B20 sensor may be installed in humid conditions, under water, sealed in concrete or placed under the floor. Connecting devices and sensors other than DS18B20 is not allowed. Never cut, shorten or bend the antenna. Its length is suited to the band at which the system functions. Both buttons must be pressed simultaneously to trigger tamper functionality. Use reset procedure only if the primary controller is missing or inoperable. Certain device removal can be achieved by the procedure of removing. Make sure the TMP button is intact. Wait 3 seconds until the LED starts blinking. Then repeat the inclusion procedure. Sending relevant information may take even a few minutes. It is not recommended to associate more than 10 devices in general, as the response time to control commands depends on the number of associated devices. In extreme cases, system response may be delayed. Sending BASIC SET or ALARM command frames. 2nd Association Group is assigned to TMP button. Once the button is released, ALARM GENERIC frame is sent to associated devices. 3rd Association Group reports the device status and allows for assigning single device only the main controller by default. It is not recommended to associate more than 10 devices in general, as the response time to control commands depends on the number of associated devices. In extreme cases, system response may be delayed. After a successful communication attempt, the sensor will update configuration parameters, associations and settings and will go into standby mode. After failed communication attempt e.g.

lack of ZWave range the device will go into standby mode and retry to establish connection with the main controller after the next time interval. Wake up may be still performed manually by a single TMP button click. Parameter inactive in external button mode parameter 1 set to 1. Disabling events might extend battery life. Commands represent the values of BASIC SET command frames. Parameter is inactive in external button mode parameter 1 set to 1. In case of associating the Dimmer or Roller Shutter module, values 199 allow to set an associated device to a specified level. In case of associating the Dimmer or Roller Shutter module, values 199 allow to set an associated device to a specified level. If an external sensor is connected to IN input, it is possible to choose its

functionality. Otherwise it is recommended to set this parameter to default value. The shorter the time, the more frequently the temperature will be measured, but the battery life will shorten. Thresholds are set in parameters 55 and 56. To deactivate all scenes set the value to 0. To activate all scenes set the value to 3903. They are not repeated by the mesh network. Parameter is active only in ZWave network security mode. It does not apply to 1st group "Lifeline". After successful communication attempt, a sensor will update configuration parameters, associations and settings, and then will go into standby mode. After failed communication attempt eg. Wake up may be still performed manually by triple clicking the TMP button. The parameter allows user to specify additional time, after which the input IN alarm is cancelled once its violation has ceased. In case of the Dimmer module it means activating the device and setting it to the previously stored condition, e.g. when Dimmer is set to 30%, deactivated and then reactivated using 255 command, it will be automatically set to the previous condition i.e. 30%.

Information on alarm violation or activation commands for devices from association groups are always sent. If the temperatures differ by the set value or more, a report with the current temperature value is sent to the device assigned to association group no. 3. Information is sent to devices assigned to association group no. 3. The user may expand the functionality of a button connected to IN input by distinguishing the sequence of it being pushed. For example double click would trigger the "goodnight" scene and triple click would trigger the "morning" scene. To fully use the possibilities offered by the parameter no.14 it is recommended to use a momentary or a toggle switch parameter no.3. In case of Wake Up Interval set for 4000 seconds temperature sensor will be checked every 5 minutes. They are not two separate switches. It is only one switch with two buttons. To activate the switch both buttons should be pushed at the same time, so in this case plastic cover should be closed. No, there is no an output module. Not at the same time. When using IN input do not use magnetic input. No, this is a battery device so it cannot be a repeater. However it can send the signal which will be repeated by other nodes up to 4 nodes. No, resetting the module procedure removes only controller's ID from the module but not module from the controller. What should I do Turn on the controller in deleting mode and perform the same as during the adding procedure. Click 3 times on TMP button. Please make sure that plastic cover is closed. In default settings it should work up to 2 years, but it also depends on the usage. Can it be used outside. Some patients infected with COVID19 suffer from lung and heart damage. and other formats are not supported. Read switch ilog description for more details. The default entry defines the place in order list for files not matched with other entries in this file. If rarfiles.lst contains such two masks that all files matched by one mask are also matched by another, that mask which matches a smaller subset of file names will have higher priority regardless of its position in the list.

The command is a string or a single letter which commands RAR to perform a corresponding action. Switches are designed to modify the way RAR performs the action. Other parameters are archive name and files to be archived into or extracted from the archive. File names should start at the first column. For example, you may create backup.lst containing the following strings Comments are displayed while the archive is being processed. Comment length is limited to 62000 bytes The following command adds a comment from info.txt file File comment length is limited to 32767 bytes. It is especially convenient for switches like av, cl, cu, tl, which do not have a dedicated command. Please note if the processing of this command results in removing all the files from the archive, the empty archive would be removed. Updates those files changed since they were packed to the archive. This command will not add new files to the archive. Moving files and directories results in the files and directories being erased upon successful completion of the packing operation. It may be important when you need to send a file to stdout for use in pipes. During this stage only the archive structure is reconstructed and it is impossible to recover files which fail the CRC validation, it is still possible, however, to recover undamaged files, which were inaccessible due to the broken archive structure. Mostly this is useful for nonsolid archives. For example It is especially important when using wildcards. Such a command is potentially dangerous, because a wrong wildcard may corrupt all archived names. Optionally, redundant information recovery record may be added to an archive. This will cause a small increase of the archive size and helps to recover archived files in case of floppy disk failure or data losses of any other kind. A recovery record contains up to 524288 recovery sectors. Just append the percent character to the command parameter.

For example This value may be lower in cases of multiple damage. This command makes sense only for multivolume archives and you need to specify the name of the first volume in the set as the archive name. For example Reposting recovery volumes instead of usual volumes may reduce the total number of files to repost. For example, if you have 30 volumes and 3 recovery volumes, you are able to reconstruct any 3 missing volumes. If the number of .rev files is less than the number of missing volumes, reconstructing is impossible. The total number of usual and recovery volumes must not exceed 255. Recovery algorithm uses data stored both in REV files and in RAR volumes to rebuild missing RAR volumes. So if you modify RAR volumes, for example, lock them, after creating REV files, recovery process will fail. You may also append a percent character to this parameter, in such case the number of creating .rev files will be equal to this percent taken from the total number of RAR volumes. For example For example, volname.part03.rar will be renamed to volname.part03.rar.bad. The archive is merged with a SFX module using a module in file default.sfx or specified in the switch. RAR creates a new archive without SFX module, the original SFX archive is not deleted. This command performs a dummy file extraction, writing nothing to the output stream, in order to validate the specified files. Adds files not yet in the archive and updates files that have been changed since they were packed into the archive. Files are listed using the format full pathname, file comment, original and compressed size, compression ratio, last update date and time, attributes, CRC, compression method and minimum RAR version required to extract. AV check and comment show are disabled. The same as when none or an illegal command line option is entered. By default RAR places files from all archives in the same directory, but this switch creates a separate directory for files unpacked from each archive.

Useful for daily backups. The format string may include the following characters For example, use WW for two digit week number or YYYY to define four digit year. This text is inserted into archive

name. Depending on the format string and time passed since previous use, generated and existing archive names may mismatch. In this case RAR will create a new archive instead of updating the already existing. It allows to generate unique names even when YYYYMMDD format mask used more than once in the same day. This switch preserves attributes assigned by operating system to a newly created file. This path is merged to file names when adding files to an archive and removed from file names when extracting. It is convenient to use this switch in combination with `u` update to synchronize contents of an archive and an archiving directory. It looks similar to creating a new archive, but with one important exception: if no files are modified since the last backup, the operation is performed much faster than the creation of a new archive. RAR will put, in every new and updated archive, information concerning the creator, last update time and archive name. We recommend to use this RAR feature as informational only, like a special archive comment. Avoid it in situations, when accurate information about archive creator is important. Please contact your local distribution site or the worldwide distribution center. This switch in combination with the command `"A"` performs the same action as the command `"M"`. Available in Windows version only. Before deleting file data are overwritten by zero bytes to prevent recovery of deleted files. When extracting such archives, RAR creates nonempty directories basing on paths of files contained in them. Information about empty directories is lost. All attributes of nonempty directories except a name, access rights, streams, etc. will be lost as well, so use this switch only if you do not need to preserve such information.

It allows to skip external data like digital signatures safely, but in some special cases it may be useful to disable this feature. For example, if an archive is transferred between two systems via an unreliable link and at the same time a sender adds new files to it, it may be important to be sure that the already received file part will not be modified on the other end between transfer sessions. This switch enables files to be added to an archive without including the path information. This could, of course, result in multiple files existing in the archive with the same name. Do not store the path entered in the command line. Store full file paths except a drive letter and leading path separator when archiving. Win32 version only. Drive separators colons are replaced by underscore characters. If the user also specified a destination path, it will be ignored. For example, you may run `In other words, use it if you have created an archive yourself or completely trust its author.` This switch allows to overwrite any file in any location on your computer including important system files and should normally be used only for the purpose of backup and restore. So if result of bitwise AND between file attributes and mask is nonzero, file would not be processed. Only those files which have at least one attribute specified in the mask will be processed. The order in which the attributes are given is not significant. Unix version supports `D` and `V` symbols to define directory and device attributes. This switch encrypts all sensitive archive areas including file data, file names, sizes, attributes, comments and other blocks, so it provides a higher security level. Without a password it is impossible to view even the list of files in archive encrypted with `hp`. Win32 version only. You need to have a MAPI compliant email client to use this switch; most modern email programs support MAPI interface. In the latter case you will be asked for it by your email program.

It is possible to specify several addresses separated by commas or semicolons. If the switch is used when creating a multivolume archive, every volume is attached to a separate email message. The hardware must support the power off feature. Win32 version only. The switch `kb` specifies that files with CRC errors should not be deleted. In the real environment it is usually better to allow RAR to select optimal parameters automatically. Please note that improper use of this switch may lead to very serious performance and compression loss, so use it only if you clearly understand what you do. If no sign is specified, RAR will choose modules automatically, based on data and the current compression method. RAR splits multibyte channels to bytes, for example, two 16bit audio channels are considered by RAR as four channels one byte each. Usually a higher value slightly increases the compression ratio of redundant data, but only if enough memory is available to PPM. In case of lack

of memory the result may be negative. Higher order values decrease both compression and decompression speed. Higher values may increase the compression ratio, but note that PPM uses the equal memory size both to compress and decompress, so if you allocate too much memory when creating an archive, other people may have problems when decompressing it on a computer with less memory installed. Decompression will be still possible using virtual memory, but it may become very slow. If the size of the file being compressed or the total files size in the case of a solid archive is greater than the dictionary size, then increasing the dictionary size will generally increase compression ratio, decrease packing speed and increase memory requirements. It helps to reduce memory requirements without decreasing compression. This switch may be used to store already compressed files, which helps to increase archiving speed without noticeable loss in the compression ratio.

For example, `msrar;zip;jpg` will force RAR to store without compression all RAR and ZIP archives and JPG images. Available in Windows version only. It defines the recommended number of active threads for compression algorithm. If it is greater than 0, RAR will use the multithreaded version of compression algorithm providing higher speed on multiprocessor architectures. Real number of active threads can differ from the specified. Wildcards may be used both in the name and file parts of file mask. It is an additional filter limiting processed files only to those matching the include mask specified in `n` switch. It can help to reduce the command line length sometimes. Win32 version only. RAR saves Compressed file attributes when creating an archive, but does not restore them unless `oc` switch is specified. Unix version only. It is especially important in Windows 2000, XP and newer, which use streams to keep some file dependent information like file descriptions. If you use RAR to backup your NTFS disks, it is recommended to specify this switch. Note that only NTFS file system supports file based security under Windows. Can be used both when extracting and updating archived files. Following modes are available The password is casesensitive. If you omit the password on the command line, you will be prompted with message "Enter password". May be used with commands `a`, `u`, `f`, `m`, `x`, `e`, `t`, `p`, `v`, `l`, `c`, `cf` and `s`. Switch `r` prohibits it. Also RAR automatically enables the recursion if disk root without wildcards is specified as a file mask. Switch `r` disables such behavior. Following command Available only in RAR for Windows. This switch regulates system load by RAR in multitasking environment. This is a period of time that RAR gives back to the system after every read or write operation while compressing or extracting. Nonzero may be useful if you need to reduce system load even more than can be achieved with parameter.

This switch is used when creating or modifying an archive to add a data recovery record to the archive. This switch is used when creating a multivolume archive to generate recovery volumes. Solid is a special archive type. Please refer to the appendix "Glossary" for further information. Usually decreases compression, but also decreases losses in case of solid archive damages. Windows version only. Usually decreases compression, but also decreases losses from solid archive damages. If this switch is used when creating a new archive, a SelfExtracting archive using a module in file `default.sfx` or specified in the switch would be created. This switch cannot be used with `v`. Parameter must be specified in bytes. Parameter must be specified in bytes. It decreases compression, but increases chances to extract a part of data if one of several solid volumes in a volume set was lost or damaged. For example, it cannot be done when compressing one large file split between several volumes. RAR is able to reset solid statistics only between separate files, but not inside of single file. This switch is especially useful in combination with the `move` command, so files will be deleted only if the archive had been successfully tested. Format of the switch is the same as `ta`. Prevents RAR from modifying the archive date when changing an archive. Forces RAR to set the date of a changed archive to the date of the newest file in the archive. Format of the time string is Format of the switch is the same as `tn`. Optional parameter after the switch is the number between 0 and 4 controlling the file time precision. Higher precision modes add more data to archive, up to 19 additional bytes per file in case of `tsm4 tsa4 tsc4` combination. By default RAR sets only the modification time, even if

archive contains creation and last access time. Setting the modification time to unpacked files may be also disabled with tsm.

Use ts to save only the low precision modification time or to ignore all three file times on unpacking. It is not more than 2 seconds on FAT and 1 second in Unix. NTFS time precision is 0.0000001 second. Switch tsm is not required, because RAR uses it by default. Without tsm1 RAR would save the high precision modification time. It is convenient when creating volumes on removable disks. You may read more about volumes in v description. Without this switch RAR displays contents of only one single specified volume. By default this switch uses as thousands 1000 of bytes not 1024 x bytes. Predefined values can be 360, 720, 1200, 1440 or 2880 and replaced with corresponding floppy disk size. For example Using vn switch it is possible to switch to another, extension based naming scheme, where the first volume file in a multivolume set has the extension.rar, following volumes are numbered from.r00 to.r99. If there is no next volume on the drive and the disk is removable, the user will be prompted with The switch applies only to removable media, the hard disk cannot be erased using this switch. But if you specify a file name exactly, including a version, it will be also unpacked. In this case a version number is not removed from unpacked file names. You may also extract a concrete file version specifying its number as ver parameter. It will tell RAR to unpack only this version and remove a version number from file names. Old file versions exceeding this threshold will be removed. Using vn switch it is possible to switch to another, extension based naming scheme, where the first volume file in a multivolume set has the extension.rar, following volumes are numbered from.r00 to.r99. It may have sense, if you are going to unpack an archive under the plain MS DOS, which does not allow more than one dot in a file name. This switch forces RAR to ask such confirmation always.
